

December 2022

ASSET MODERNIZATION

The purpose of this communication is to describe, validate and update the Asset Modernization investment that Northern has made and will continue to make to ensure the safety and reliability of its system, as well as to comply with applicable regulatory requirements. By the end of 2022, Northern is expected to have completed \$1.2 billion of Asset Modernization investment from the beginning of the program. Over the next ten years, Northern is expected to invest another \$2.3 billion, for a total overall investment of over \$3.5 billion in Asset Modernization since program inception.

The Asset Modernization program is intended to significantly reduce the reliability risk inherent in Northern's vintage facilities and the integrity risks that have plagued other operators. Northern classifies its Asset Modernization projects into five broad project classifications: (1) Pipeline Assessment; (2) Compression Replacement; (3) LNG Equipment Replacement; (4) Underground Storage Integrity; and (5) Vintage Pipeline Replacement.

The program impacts Northern's operations and maintenance (O&M) expenses as well. While some of the projects result in a reduction to O&M, the net impact is an increase to O&M expenses. The primary O&M cost driver of Asset Modernization is the Pipeline Assessment category, which causes substantial increases to Northern's costs of in-line inspections due to the increased mileage of inspectable pipeline and increased inspection requirements to comply with updated pipeline safety laws and regulations.

Facilities of equivalent capacity are installed to replace the capacity of retired pipeline and compressor units. Incremental capacity is not generally created through these replacements; however, Northern has and will continue to pursue efficiencies through project coordination with expansion open seasons.

Background

The Northern pipeline system was built in phases, beginning in the 1930s, with system expansions developed to meet customer needs. Northern currently operates approximately 14,300 miles of pipeline and 55 compressor stations. Approximately 85% of the pipeline mileage was installed prior to the first enactment of federal pipeline safety standards in 1968. Significant expansion facilities were installed in the 1940s, 1950s and 1960s, and the utility and reliability of these expansions has been maintained with robust equipment analysis, equipment maintenance programs and proactive parts management. While these facilities are still dependable, they have a finite life, and vendor/product support is no longer available for older equipment as equipment manufacturers move to support newer technology.

Northern has been working to maintain and modernize its system for many years, repairing and replacing components of its transmission and storage plant to ensure continued reliability. Examples of Northern's modernization efforts over the last seven years include:

- Replacing compressor units at seven stations: the Brownfield, Texas; Spraberry, Texas; Farmington, Minnesota; Beatrice, Nebraska; Ogden, Iowa; Mullinville, Kansas; and Bushton, Kansas compressor stations.
- Modernizing equipment at Northern's liquefied natural gas (LNG) storage facilities in Garner, Iowa and Wrenshall, Minnesota. Northern replaced the molecular sieve vessels in 2015 and 2016 at the Garner and Wrenshall facilities respectively. As part of an ongoing program to replace obsolescent, original equipment at the Garner facility, Northern also replaced the 480-volt motor control center in 2022, which was installed in 1978. Plans for 2023 include replacement of the 4,160-volt motor control center and the cold box compressor unit.
- Abandoning approximately 580 miles of 1930s vintage A-mainline from Bushton, Kansas to Ogden, Iowa and Palmyra, Nebraska to Sioux Falls, South Dakota as part of the vintage pipeline replacement program.
- Modifying pipelines to make nearly 2,100 miles of large-diameter pipe inspectable, increasing the number of miles modified per year from 164 miles in 2016, to 342 miles in 2022, averaging 361 miles a year since 2019.

While these efforts have maintained the reliability of Northern's system, Northern must continue to implement broader replacement programs for specific Asset Modernization needs.

Asset Modernization as a category was created in 2016 to capture and characterize the significant increase in costs related to the modernization projects. Northern's Asset Modernization program was designed using FERC's policy statement on Cost Recovery Mechanisms for Modernization of Natural Gas Facilities, and it necessarily represents a significant expansion of Northern's historical maintenance and upgrade programs due to the age of the system and updated safety laws and regulations. The costs are captured in the following budget summary categories:

- Pipeline Assessment
- Maximum Allowable Operating Pressure Reconfirmation
- Remote Mitigation Valves
- Compression Replacement
- LNG Equipment Replacement
- Underground Storage Integrity
- Vintage Pipeline Replacement

The Maximum Allowable Operating Pressure (MAOP) Reconfirmation and Remote Mitigation Valve programs are new categories within Northern's Asset Modernization project portfolio. These categories have been added to better capture and understand additional facets of Northern's modernization efforts and are further explained in sections below.

Northern must continue with this Asset Modernization effort to ensure its industry-leading service reliability will not suffer due to increased outage quantities and duration, as well as to comply with increased legal and regulatory requirements as further discussed below. In addition, Asset Modernization is required to ensure continued pipeline integrity and avoid unacceptable pipeline incidents. The industry in general, including distribution utilities, have undertaken similar modernization efforts to replace vintage facilities such as cast-iron pipelines, which pose similar threats to service reliability and public safety.

Capital Expenditures Summary

Northern is completing \$293 million of Asset Modernization projects in 2022, compared with \$290 million in projects completed in 2021. Asset Modernization projects totaling \$2.3 billion are planned from 2023 through 2032, approximately \$327 million greater than the 10-year plan reported in 2021, due to the addition of MAOP reconfirmation projects.

Asset Modernization does not completely replace all vintage facilities on the Northern system, as a majority of the approximately 14,300 miles of pipeline and 184 compressor units will continue to be maintained through more traditional means. The Asset Modernization program only addresses facilities and systems at the end of their useful lives or where replacement or inspections are required by federal regulations.

Budget Summary Categories

Pipeline Assessment

On October 1, 2019, the Pipeline and Hazardous Materials Safety Administration (PHMSA) issued the first of a three-part final rule titled the Safety of Gas Transmission Pipelines: MAOP Reconfirmation, Expansion of Assessment Requirements and Other Related Amendments (Mega Rule). The rule focuses primarily on reconfirming maximum allowable operating pressures and expanding assessment requirements to include the newly defined moderate consequence areas. The rule expands pipeline integrity assessment requirements by defining moderate consequence areas and requiring integrity assessments. The rule requires MAOP reconfirmation in high consequence areas, moderate consequence areas, and Class 3 locations that operate at or above 30% specified minimum yield strength.

The Pipeline Assessment category captures significant capital expenditures driven by the need to modernize infrastructure for the purpose of accommodating the internal inspection of pipelines and to comply with increased requirements imposed by new and updated pipeline safety laws and regulations. The costs for pipeline assessments fall into two major categories:

- (1) Pipeline modification projects on Class 3 pipeline segments that are operating above 30% specified minimum yield strength not previously assessed with in-line inspection tools to meet requirements of the Mega Rule.

- (2) Pipeline modifications to increase the percent of the system that is in-line inspection capable with the focus on large-diameter pipelines (greater than 16-inch-diameter) and pipelines operating above 30% of their specified minimum yield strength in areas outside of high consequence areas, and to assist with meeting existing PHMSA MAOP Regulations and other regulations.

As shown in Exhibit No. 1, Northern plans to invest \$554 million in Pipeline Assessment projects during the next 10 years. The large-diameter pipeline modifications are anticipated to be largely complete by 2030 and all projects mandated by the Mega Rule will be completed by 2035.

These projects will continue to have a significant O&M expense impact that materializes as a result of subsequent in-line inspections, tool data verification excavations and repair work associated with the inspections. These costs are not included in the capital portion of the work required to make the modifications, and are extremely variable based on the line length, tool technology required and results of the inspection. Expenses associated with the inspections will be recurring, normally five to 10 years in frequency, depending on the condition of the line and regulatory requirement.

MAOP Reconfirmation

MAOP reconfirmation is a new classification of Asset Modernization. As noted above, the Mega Rule, issued by PHMSA in 2019, requires MAOP reconfirmation in high consequence areas, moderate consequence areas, and Class 3 locations that operate at or above 30% specified minimum yield strength. While Northern has conducted many reviews to confirm MAOP of its pipelines, if no pressure test record exists for a pipeline, the MAOP must be re-established by completion of a pressure test, reducing pressure, an engineering critical assessment or through pipe replacement. The pipe replacement projects are being captured as part of Northern's Asset Modernization program as these replacements increase pipeline integrity and reliability in areas of consequence.

The majority of Northern's pipelines impacted by the Mega Rule have existing pressure tests and material documentation in support of the MAOP. In 2019, engineering analysis concluded, of approximately 473 miles of pipeline within high consequence areas, moderate consequence areas, and Class 3 locations, 130 miles of pipe required re-establishment of MAOP and to-date, Northern has approximately 93 miles remaining to re-establish.

As shown in Exhibit No. 1, Northern plans to invest \$339 million in MAOP replacement projects during the next 10 years. Per the PHMSA rule, half of these projects must be completed by 2029, with the entire program complete in 2034.

Remote Mitigation Valves

On April 8, 2022, PHMSA revised the Federal Pipeline Safety Regulations applicable to most newly constructed and entirely replaced onshore gas transmission pipelines with

diameters of 6-inches or greater. In the revised regulations, PHMSA requires installation of remote mitigation valves, such as an automatic shut-off valve (ASV) or a remote-control valve (RCV), to minimize the volume of gas released from a pipeline in the case of a pipeline rupture, helping to mitigate public safety and environmental consequences. The final rule establishes requirements for remote mitigation valves spacing, maintenance and inspection and applies to construction after April 10, 2023.

Northern is reviewing planned projects to ensure compliance with the new rule. Currently, Northern anticipates spending approximately \$2.4 million per year on projects to install RCVs on existing lines in consequence areas. These projects will be ongoing as Northern assesses risks and opportunities to mitigate the risks on the existing system. Remote mitigation valves will also be installed as required on new pipeline segments and included with the original project (excluded from Asset Modernization).

Compression Replacement

The Compression Replacement category represents the costs to replace vintage compressor units throughout the system, with the priority placed on units based on vintage, criticality to pipeline operations, historical reliability concerns and outlook for future maintainability. The program also pertains to critical compression support auxiliary equipment and infrastructure.

Northern has 99 compression units between 50 and 75 years old. As these facilities reach obsolescence, parts become more difficult – if not impossible – to obtain. In fact, Northern has had to manufacture many of its own replacement parts for obsolete units. Unexpected failures can lead to longer outages while parts are located or fabricated, negatively impacting service to customers. Northern's compression maintenance costs have increased substantially as a consequence of an aging fleet of compressor units.

To fulfill customer commitments, it is paramount that Northern's compression fleet maintain high reliability. With over half of these units reaching 80-years old and some surpassing 90-years old in the next 20 years, a replacement program has been implemented that will mitigate short- and long-term customer reliability risks.

The current Asset Modernization plan includes replacement of up to 45 units over the next ten years. This represents 45% of the 99 vintage compression units and approximately 24% of Northern's 184 total compression units. Fifteen units have been replaced under this program since 2016.

The units targeted for modernization are spread across Northern's system and are included in both the field and market areas. As a result, many units on the main trunks of the system have replacement plans in the near-term or have already been replaced. Vintage units along the main corridor of Northern's pipeline system at Brownfield, Texas; Spraberry, Texas; Bushton, Kansas; Mullinville, Kansas; Beatrice, Nebraska; Ogden, Iowa; and Farmington, Minnesota, have been or will be replaced in the near-term to ensure continued reliable service to customers and the public.

Specifically, the Beatrice, Nebraska; Mullinville, Kansas; and Bushton, Kansas, units were replaced in 2016, 2019 and 2020 respectively, to eliminate the last three General Electric LM 1500 units on the Northern system. These obsolete units were becoming increasingly unreliable and difficult to effectively repair, were nearing the end of their useful life for critical rotating components and were only supported by one service entity in the industry.

The Ogden, Iowa, early 1950s vintage horizontal reciprocating compressor units, replaced in 2021, were also obsolete and becoming unreliable. These units were generally unsupported within the industry and most pipeline companies in North America replaced vintage horizontal compressors years ago, although Northern was able to extract several years of additional life out of the units through its robust maintenance program and by machining obsolete parts, as needed, before replacing them.

In addition to maintenance and reliability concerns, vintage units also require replacement to comply with more rigorous environmental regulations. For example, the Farmington, Minnesota, early 1960s vintage reciprocating Unit Nos. 1-5 were replaced in 2021, as the station would otherwise fail to meet current emissions limits set by the Minnesota Pollution Control Agency.

Two early 1950's vintage units at the Spraberry, Texas, compressor were replaced in 2022 due to reliability and unit performance concerns. An early 1960's vintage General Electric Frame 3 turbine at the Brownfield, Texas, compressor station was also replaced in 2022. This replacement will reduce service reliability risk to customers at a critical location and give Northern access to critical spare parts such as rotors, casings, and turbine wheels that are not generally available within the industry and will help extend the service life of nine additional like turbines that remain in-service across the Northern compression fleet.

As shown in Exhibit No. 1, Northern plans to invest \$567 million in Compression Replacement projects during the next 10 years. Northern will replace at least two units per year to allow replacement of units and critical auxiliary equipment at a rate necessary to largely avoid relying on units greater than 90 years old. Such units would present significant reliability risk to Northern's customers, as equipment of this vintage would be very difficult to maintain, repair, and overhaul given end of useful life of critical components not normally or easily replaced, obsolescence of spare parts, and lack of industry service options. This level of investment also allows Northern to continue to modernize its compression fleet to ensure any future federal or state emissions compliance mandates can be achieved in a timely fashion. This program will continue beyond the 10-year outlook as compressor units age and are replaced.

LNG Replacement

Northern operates peak shaving LNG facilities at Wrenshall, Minnesota, and Garner, Iowa. The Wrenshall LNG station was installed in 1974, and the Garner LNG station was installed in 1977. These cryogenic facilities each have 2.1 billion cubic feet of LNG storage

and can vaporize the stored liquefied gas into useable pipeline gas at a total rate of 300,000 Mcf/day through three vaporization trains. The liquefaction equipment can replace vaporized storage gas at a rate of 12,000-17,000 Mcf/day.

The LNG facilities are used as operational storage to support the delivery of hourly peaking volumes, to support the simultaneous receipt and delivery of transportation quantities, and to balance line pack on Northern's system. While vaporization ensures contractual deliveries are not jeopardized, the resultant system flexibility has also proven routinely critical for customer reliability in winter.

This category represents the cost to replace major equipment components at the LNG plants. LNG plant operations also involve significant electrical and electronic control equipment. Electrical system modernization increases the safety and reliability of station motor control centers and electrical power distribution to critical vaporization and liquefaction equipment.

The original facilities were installed in the 1970's, and as a result, much of the equipment has reached the end of its life. Northern has historically maintained older equipment and replaced parts or subsystems versus wholesale replacements. However, in recent years, routine maintenance projects have proven insufficient, and Northern began replacing larger systems or pieces of equipment out of necessity. This equipment either displayed integrity concerns or required replacement due to obsolescence and unavailability of parts.

Also, as part of the ongoing modernization and replacement of original equipment at the Garner facility, the 4160-volt motor control replacement project will be completed in 2023 with the cold box heat exchanger and the noted refrigeration compressor replacement. The 480-volt motor control replacement project was completed in 2022.

At the Wrenshall LNG facility, vaporizer replacement is planned for 2025. This project will replace all three of Wrenshall's direct fired, submerged combustion LNG vaporizers which are original to the facility and have become less reliable and more costly to maintain. The new replacement LNG vaporizers will help to reduce maintenance costs as well as improve vaporizer reliability. Added to the 10-year plan is the replacement in 2026 of the current 5,900 gallon liquid nitrogen storage tank and associated vaporizer, both original to the facility. The nitrogen vaporizer will be increased in size to better meet the capacity requirements of the various nitrogen system uses throughout the facility. Replacement of the reactivation gas cooler and purification filters, also original to the facility and nearing the end of serviceable life, are scheduled for replacement in 2027 and 2028.

As shown in Exhibit No. 1, Northern plans to invest \$58 million in LNG Replacement projects during the next 10 years. These projects are expected to continue intermittently beyond the 10-year outlook to maintain system reliability.

Underground Storage Integrity

The Underground Storage Integrity category includes projects to ensure compliance with a new PHMSA rule. In 2020, the Safety of Natural Gas Underground Storage Final Rule became effective. This rule gave PHMSA new jurisdiction over the underground storage field wells and reservoirs. The new regulations incorporated new industry standards into the pipeline safety regulation that operators are required to implement, including American Petroleum Institute API- Recommended Practice 1171- Functional Integrity of Natural Gas Storage in Depleted Hydrocarbon and Aquifer Reservoirs. To comply with the regulations, Northern revised its reservoir integrity management plan to include new operating procedures and engineering standards and also created the Underground Storage Integrity capital expenditure program.

Under its reservoir integrity management plan required per this rulemaking, Northern will complete additional observation and natural gas withdrawal wells in the Redfield, Iowa, underground storage field. Additionally, Northern will establish and maintain an undisturbed buffer zone around the storage field to further ensure field integrity. Northern completed the installation of a withdrawal well in 2020 and in 2022.

A notable addition to the 10-year Underground Storage Asset Modernization program is the plan to add a natural gas dehydration and hydrogen sulfide treatment facility to the Lyons, Kansas underground storage system. Currently, Northern performs dehydration and hydrogen sulfide treatment on the storage gas at a facility in Bushton, Kansas, 16-miles away. While Northern has maintained the 1974 vintage facility in Bushton, maintenance efforts and costs have increased substantially in recent years. A new facility located in Lyons, Kansas will optimize gas treatment at the withdrawal point of the storage field similar to Northern's other underground storage facilities. This eliminates the shipment of untreated gas to the Bushton, Kansas facility. Additionally, the new treatment facility will be constructed according to current codes, regulations and best practices, which will increase the energy efficiency of the facility as well as employee health and safety.

As shown in Exhibit No. 1, Northern plans to invest \$60 million in Underground Storage Integrity projects during the next 10 years. These projects are expected to continue beyond the 10-year outlook as additional withdrawal well replacements or observation wells are needed.

The new wells will slightly increase storage O&M expense to maintain the new facilities.

Vintage Pipeline Replacement

The Vintage Pipeline Replacement projects will replace existing aged pipelines by abandoning mechanically coupled and acetylene-welded mainlines and branch lines and installing facilities to replace the associated capacity. To date, Northern has abandoned approximately 650 miles of vintage mainline and branch line as part of this program, with an additional 330 miles of mainline planned for abandonment through 2029.

Mechanically coupled pipeline joint technology, originating in 1891, and acetylene-welded pipeline technology, initially used for pipeline construction beginning in 1911, were historically used in natural gas pipeline applications but were largely discontinued by 1940. These construction techniques were also used in the initial construction of Northern's system. By 1933, most cross-country pipelines were being constructed with the superior-strength electric resistance arc-welded girth joints, as mechanically coupled and acetylene-welded joints are subject to failure from ground movement and can frequently leak natural gas. Furthermore, these joint types are not compatible with modern pipeline integrity assessment methods; they cannot be inspected with in-line inspection tools nor hydrostatically tested without incurring significant quantities of leaks. Additionally, much of this pipe is uncoated and is therefore susceptible to external corrosion.

While Northern has successfully operated these facilities for nearly 90 years, these pipelines have reached the end of their useful life. As shown in Exhibit No. 1, Northern plans to invest \$669 million in Vintage Pipeline Replacement projects during the next 10 years. This program is anticipated to continue for approximately 15 years, with large-diameter mainlines being replaced within the next seven years and the program's focus shifting to branch lines and ultimately small-diameter pipelines. The total program cost is currently estimated at \$1.2 billion through 2032 although updates on the total will be provided as out-year projects are more fully prioritized.

In addition to increasing system reliability, the Vintage Pipeline Replacement category is also creating additional system efficiencies. For example, with the additional compression installed at the Beatrice, Nebraska, compressor station in 2021 to replace the capacity reduction associated with adjacent pipeline retirement, there is an expected \$0.7 million decrease in compressor fuel expense due to the resulting system optimization that reduced the need for compressor use at the Palmyra, Nebraska, compressor station.

Conclusion

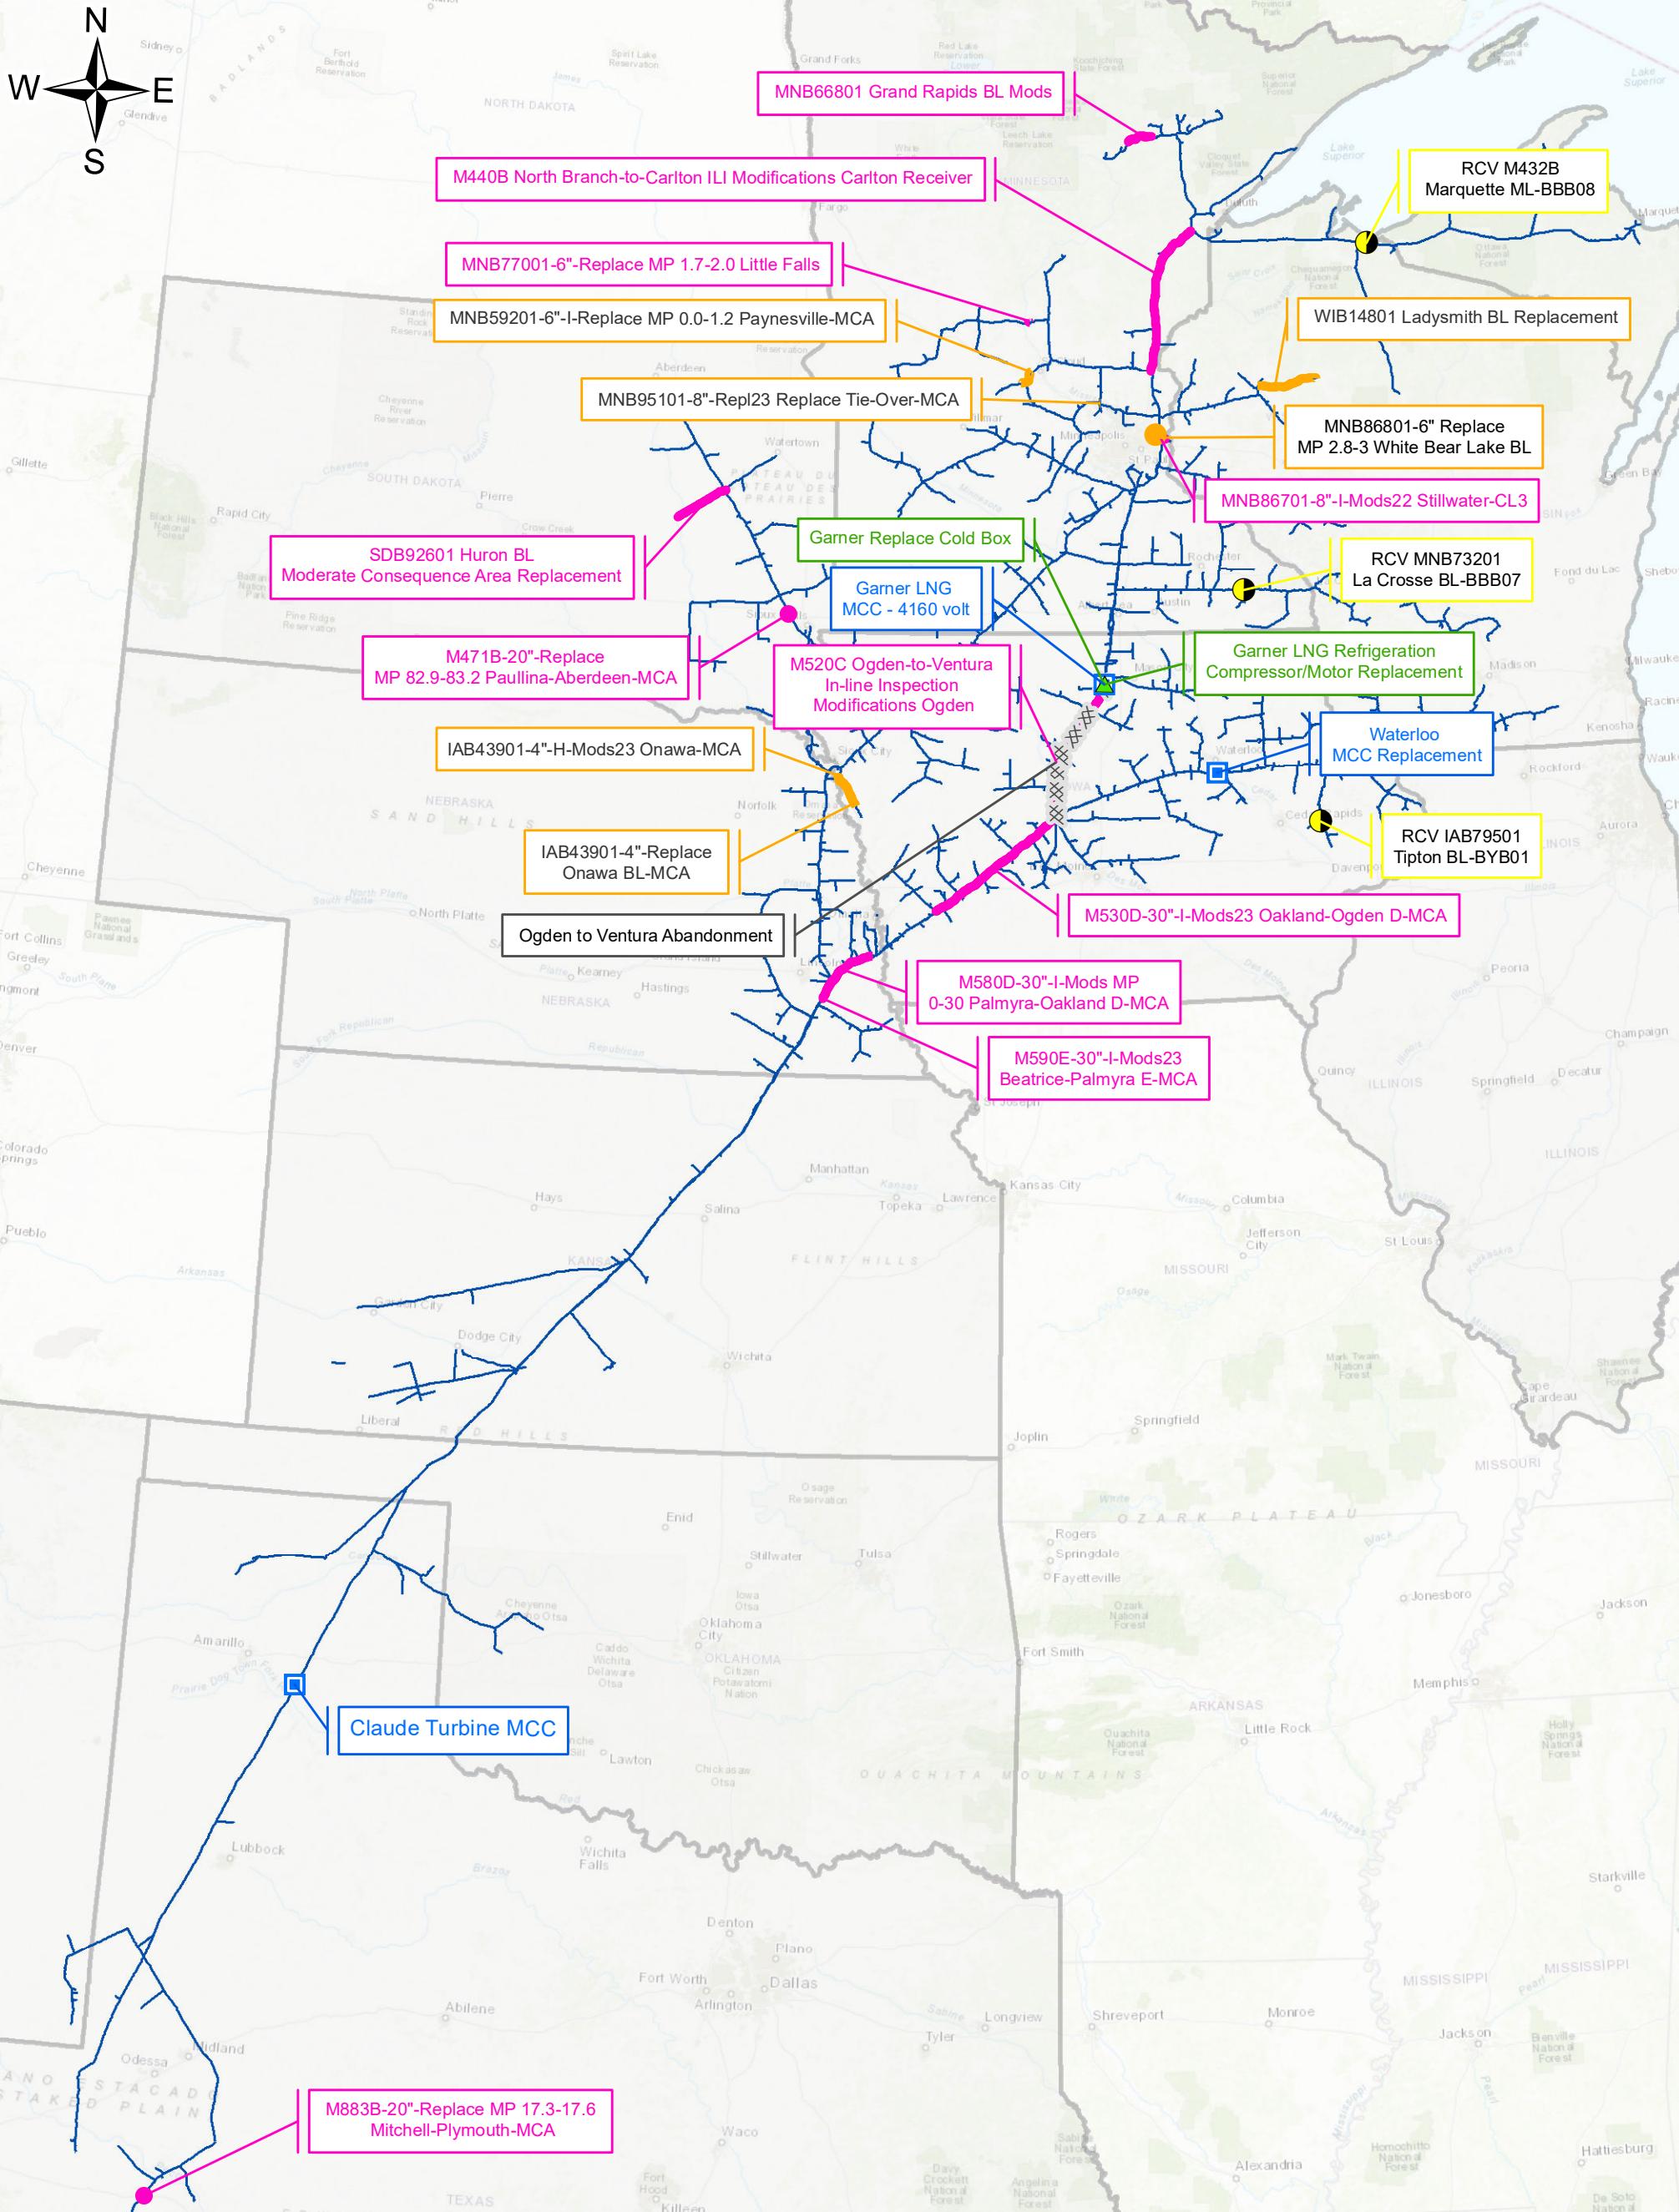

In summary, Northern will invest approximately \$2.3 billion over the next 10 years to modernize the pipeline, compression, underground storage and LNG facilities as described above, resulting in improvements to system integrity, reliability, efficiency and public safety.
